## Guide to Traffic Management Part 1: Introduction to Traffic Management

**Third edition project manager:** Jill Hislop

**Third edition prepared by:** Clarissa Han and James Luk

**First and second edition prepared by:** Peter Croft

Third edition May 2015

Second edition November 2009

First edition published November 2007

This third edition includes updated descriptions of each Part in Section 2 and Table 2.1. It also includes additional information on the functional road hierarchy in Section 3.4 and a new Section 4.5 on road environment safety. This edition also includes updated referencing to relevant legislations, standards and guidelines.

**ISBN** 978-1-925294-38-5

**Pages** 13

**Austrroads Project No.** NT2004

**Austrroads Publication No.** AGTM01-15

### Keywords

Traffic management, road hierarchy, traffic control, traffic regulations

### Abstract

The Austrroads *Guide to Traffic Management* has 13 Parts and provides comprehensive coverage of traffic management guidance for practitioners involved in traffic engineering, road design and road safety.

*Part 1: Introduction to Traffic Management* provides an introduction to the discipline of traffic management and an overview of the structure and content of the Guide. It outlines the breadth of the subject, the distribution of content among the various Parts of the Guide, and the relationship with other Guides such as those for *Road Design*, *Road Safety* and *Road Transport Planning*.

Part 1 introduces traffic management in a practical context, and presents fundamental definitions, principles and objectives. It introduces functional road hierarchy as an essential concept, and outlines the basic elements of traffic management and their application. It provides an overview of how the various parts of the Guide would typically be used by a wide range of practitioners.

### About Austrroads

Austrroads' purpose is to:

- promote improved Australian and New Zealand transport outcomes
- provide expert technical input to national policy development on road and road transport issues
- promote improved practice and capability by road agencies.
- promote consistency in road and road agency operations.

Austrroads membership comprises:

- Roads and Maritime Services New South Wales
- Roads Corporation Victoria
- Department of Transport and Main Roads Queensland
- Main Roads Western Australia
- Department of Planning, Transport and Infrastructure South Australia
- Department of State Growth Tasmania
- Department of Transport Northern Territory
- Territory and Municipal Services Directorate, Australian Capital Territory
- Commonwealth Department of Infrastructure and Regional Development
- Australian Local Government Association
- New Zealand Transport Agency.

The success of Austrroads is derived from the collaboration of member organisations and others in the road industry. It aims to be the Australasian leader in providing high quality information, advice and fostering research in the road transport sector.

This Guide is produced by Austrroads as a general guide. Its application is discretionary. Road authorities may vary their practice according to local circumstances and policies. Austrroads believes this publication to be correct at the time of printing and does not accept responsibility for any consequences arising from the use of information herein. Readers should rely on their own skill and judgement to apply information to particular issues.

## Foreword

Austrroads works towards uniformity of practice in respect of design, construction and user aspects of roads and bridges and with this purpose in view, publishes guides and procedures.

The *Guide to Traffic Management* continues the tradition of previous Austrroads publications, such as the *Guide to Traffic Engineering Practice*, first published in 1965, in providing a practical guide to traffic engineering for road and transport engineers in road agencies, local government, and engineering consultancies, and as a reference for engineering students.

The Guide is available as 13 separate Parts, as follows:

- Part 1: Introduction to Traffic Management
- Part 2: Traffic Theory
- Part 3: Traffic Studies and Analysis
- Part 4: Network Management
- Part 5: Road Management
- Part 6: Intersections, Interchanges and Crossings
- Part 7: Traffic Management in Activity Centres
- Part 8: Local Area Traffic Management
- Part 9: Traffic Operations
- Part 10: Traffic Control and Communication Devices
- Part 11: Parking
- Part 12: Traffic Impacts of Developments
- Part 13: Road Environment Safety.

The information contained in the various Parts is intended to be used as a guide to good practice. Discretion and judgement should be exercised in the light of many factors that may influence the choice of traffic engineering treatment in any given situation.

These guidelines make reference, where relevant, to current Australian Standards and are intended to supplement and otherwise assist in their interpretation and application.

# 1. Scope of the Guide

## 1.1 Purpose

The Austroads *Guide to Traffic Management* seeks to capture the contemporary traffic management practice of member organisations, including emerging techniques and technologies, and relevant international experience. It provides valuable guidance to practitioners in the implementation of efficient, safe and economical management of road traffic.

Most practical issues can be well accommodated by the approach outlined in the Guide. Local conditions and circumstances may sometimes require unique or innovative approaches to traffic management. It is recognised that member organisations may develop and publish supplementary guidelines and manuals to cover specific situations.

Each member organisation will determine whether any other documents, including its own supplementary guidelines, take precedence over Austroads guidelines.

## 1.2 Scope

This Guide is restricted to traffic management advice and refers only briefly to issues more appropriately addressed in other Guides. The Guide recognises that the management of traffic should be based on an understanding of road design and of the capabilities and behaviour of all road users, and on the performance and characteristics of vehicles. It is difficult to discuss many aspects of traffic management without reference to road design and/or safety issues, the view is taken that within the *Guide to Traffic Management* any such reference should be brief and be supported by links to the *Guide to Road Design* and/or the *Guide to Road Safety* (refer to scope statements in the *Guide to Road Design* and the *Guide to Road Safety*).

Within the above limits, the scope of the Guide is broad, addressing both urban and rural environments and the full range of situations to be found in each, including:

- freeways/motorways, arterial roads and local roads
- all categories of road users including cars, trucks, public transport, cyclists, motorcyclists and pedestrians
- different road environments, for example, school zones, linear shopping centres along roads and roadwork zones
- other important uses of roads such as parking.

This document provides guidance to good practice in traffic management, rather than specifying mandatory practice. Aspects of practice which are mandatory (for example the form and placement of speed restriction signs) may be mentioned but their specification is the province of relevant standards or legislation. Primary references here are the Australian Standards, particularly *AS 1742 – Manual of Uniform Traffic Control Devices* (15 Parts), the Australian Road Rules and the New Zealand Land Transport Rules. Specific references are given as necessary throughout the Guide.

The Guide is aimed primarily at practitioners with responsibilities for the management of traffic on road networks. The documentation is presented in the form of a number of Parts covering specific aspects of traffic management and its implementation.

## 2. Parts of the Guide

The *Guide to Traffic Management* is divided into the following 13 Parts:

**Part 1: Introduction to Traffic Management** (this Part) provides an introduction to the discipline of traffic management and an overview of the structure and content of the Guide.

**Part 2: Traffic Theory** provides practitioners with the theoretical background necessary to appreciate the nature of traffic behaviour and to undertake analyses required in the development and assessment of both traffic management plans and road design proposals.

**Part 3: Traffic Studies and Analysis** is concerned with the collection and analysis of traffic data for the purpose of traffic management and traffic control within a network. It serves as a means to ensure some degree of consistency in conducting traffic studies and surveys. It provides guidance on the different types of traffic studies and surveys that can be undertaken, their use and application, and methods for traffic data collection and analysis.

**Part 4: Network Management** covers the broad strategies and objectives of managing road networks to provide effective traffic management for all road users, which includes heavy vehicles, public transit users, pedestrians, cyclists and private motor vehicles. It provides specific guidance on transport networks and network operations planning.

**Part 5: Road Management** is focussed on traffic management on sections of road between major intersections. It covers road space allocation, access management, lane management and speed management.

**Part 6: Intersections, Interchanges and Crossings** is focussed on traffic management at locations where various road users must join or cross another stream of traffic. It describes the appropriate use and design of the various intersection types and traffic management techniques that are applied to meet traffic management objectives, and provide efficient and safe intersections considering the needs of all road users including pedestrians, cyclists, motorcyclists, heavy vehicles and public transport.

**Part 7: Traffic Management in Activity Centres** covers principles for the planning and traffic management of activity centres and associated transport nodes.

**Part 8: Local Area Traffic Management** covers the planning and management of road space within a local area, aimed at improved safety and amenity for residents and visitors. It provides guidance on the selection, design, application and effectiveness of traffic control measures on an area-wide or at least whole-of-street basis, including the effects such schemes may have on local and arterial road networks.

**Part 9: Traffic Operations** covers the day-to-day operations that support the provision of road services to road network users. It introduces the concept of traffic operations as underpinning road user services, covers the major types of services provided and outlines the role of intelligent transport systems (ITS) in delivering these services.

**Part 10: Traffic Control and Communication Devices** provides guidance on the design and use of traffic control and communication devices, including signals, signs, markings and delineation.

**Part 11: Parking** describes the process of determining the demand for, and supply of, parking and provides a parking policy framework and how the demand should be addressed. The implementation of on-street and off-street parking including parking controls in urban centres is addressed, as is parking on rural roads and at park-and-ride facilities. Electronic parking guidance systems and signage are also described.

**Part 12: Traffic Impacts of Developments** identifies and manages the impacts on the road system arising from land use developments. It provides guidance for planners and engineers associated with the design, development and management of a variety of land use developments.

**Part 13: Road Environment Safety** is concerned with traffic management practice under a Safe System approach. It considers the role of traffic management in influencing road user behaviour, and provides guidance for practitioners on road safety aspects of traffic management.

The coverage of these Parts is summarised in Table 2.1, which is repeated in the introductory section of each of the separate Parts.

## 3. Traffic Management

### 3.1 Practical Context

The transport of people and goods is essential to the economic and social needs of the community, and substantial investment is made in a nation's road networks to facilitate this. The development and maintenance of the road network is faced with several challenges:

- continuing growth in vehicle ownership and usage
- increasing traffic congestion in urban areas
- trends toward larger (and more efficient) freight vehicles
- continuing challenge for safety improvements
- increasing concern about environmental impacts.

The central challenge is to address these often conflicting issues in a manner that balances the economic, social and environmental factors. The effective management of traffic is fundamental to making the best use of the existing road network.

Government policies on the zoning, release and development of land are also prime determinants of the amount and type of traffic generated by various land uses and required to be carried by road networks.

Increasingly, governments are recognising the importance of effective planning, development and management of land use and road networks in a more sustainable manner. This requires consideration not only of the required or desirable traffic flow conditions on different parts of the network, but also of broad issues such as the following:

- land use planning strategies
- travel demand management
- energy/fuel consumption
- urban design requirements
- safety, mobility and accessibility issues for all road users
- access to commercial, retail, industrial, residential and recreational facilities
- parking requirements
- amenity issues in residential areas
- bio-diversity issues for rural roads
- equity in respect to different user groups.

The need to consider or to resolve these often competing issues adds to the complexity of developing and implementing traffic management strategies, plans and treatments.

Some texts on traffic management and its application in the Australasian context include Underwood (1990) and Monash University (2003), and the text by Ogden (1996) covers the specific application of traffic engineering in safety management of the road environment.

## 3.2 Definition

Traffic management is the organisation, arrangement, guidance and control of both stationary and moving traffic, including pedestrians, cyclists and all types of vehicles. Its aim is to provide for the safe, orderly and efficient movement of persons and goods, and to protect and where possible, enhance the quality of the local environment on and adjacent to roads.

Traffic management is the application of specific traffic control practices, within a defined policy framework, over a length of road or an area, to achieve specified objectives which may be set by national, state or local governments. Traffic management is typified by its application over a significant area or length of route, as opposed to a specific traffic control action applied at a single location. A range of traffic management policies, practices and techniques may be appropriate to meet particular objectives.

## 3.3 Objectives and Principles

An overall aim of traffic management is to facilitate the operation of traffic on the roads with safety and efficiency, taking into account the needs of a range of road users. A broad objective may be to provide the most desirable levels of safety, accessibility, amenity and environmental quality in the area under study.

Each particular situation or area will have its own set of issues to be addressed and its own set of specific objectives. Detailed objectives can sometimes be in conflict with one another and compromise is often needed. The weighting given to particular objectives can vary from one area to another. The balance between accessibility, safety and environmental issues can also shift over time, as community values and government policies change.

Specific objectives for traffic management schemes often include the following:

- improved traffic flow conditions, reduction of congestion, (most commonly sought on arterial roads, where traffic flow efficiency objectives claim higher priority)
- enhanced safety of a route or area (arising from crash analysis or from direct community concerns)
- improved safety, mobility and accessibility for children, pedestrians and cyclists
- improved amenity of residential areas
- improved access to commercial, retail, and recreational activities
- improved road freight productivity and safety (particularly important in the achievement of economic objectives in the overall transport task)
- improved operating conditions for road-based public transport (reflecting priority for efficient movement of people rather than on movement of vehicles per se)
- Improved information for road users such a real time traveller information
- amelioration of parking problems.

An important aspect in traffic management recognises the fact that each of the objectives of any traffic management scheme is influenced primarily by the volume, composition and speed of the traffic either throughout the road network or in one or more parts of the network.

The overall volume of traffic on the whole road network is a matter for broad transport policy. It will be influenced by land use patterns, the availability of alternative transport modes, the policy position on regional-level traffic management (to moderate or accommodate traffic growth) and regional environmental objectives.

Applying the principles requires decisions on where traffic is desired, and where it is not wanted, and the consequent introduction of measures to achieve the desired distribution and flow characteristics. This requires firstly the definition of a hierarchy of roads for the study area which best suits the stated objectives. The categories of roads within the hierarchy are identified in terms of their functional description and their appropriate traffic levels.

### 3.4 Functional Road Hierarchy

The different transport and other functions served by roads, together with the needs of abutting land use, determine how they should be managed.

From a road function viewpoint there are two essential needs which must be met:

- the traffic movement, or mobility, function – providing the means by which people and goods can move from one place to another
- the access function – providing access to properties and land uses adjacent to the road.

Consideration of these two main functions of a road is fundamental to traffic management.

Ideally a given road would perform only one of these primary functions, but in practice, most roads do both. Motorways are true movement function roads, being controlled so direct access to adjacent land uses is not provided. All other roads provide some degree of access and the movement function varies greatly. On multi-function roads, traffic flow spans a wide range – and can vary during the course of a day, as can the extent of access demand.

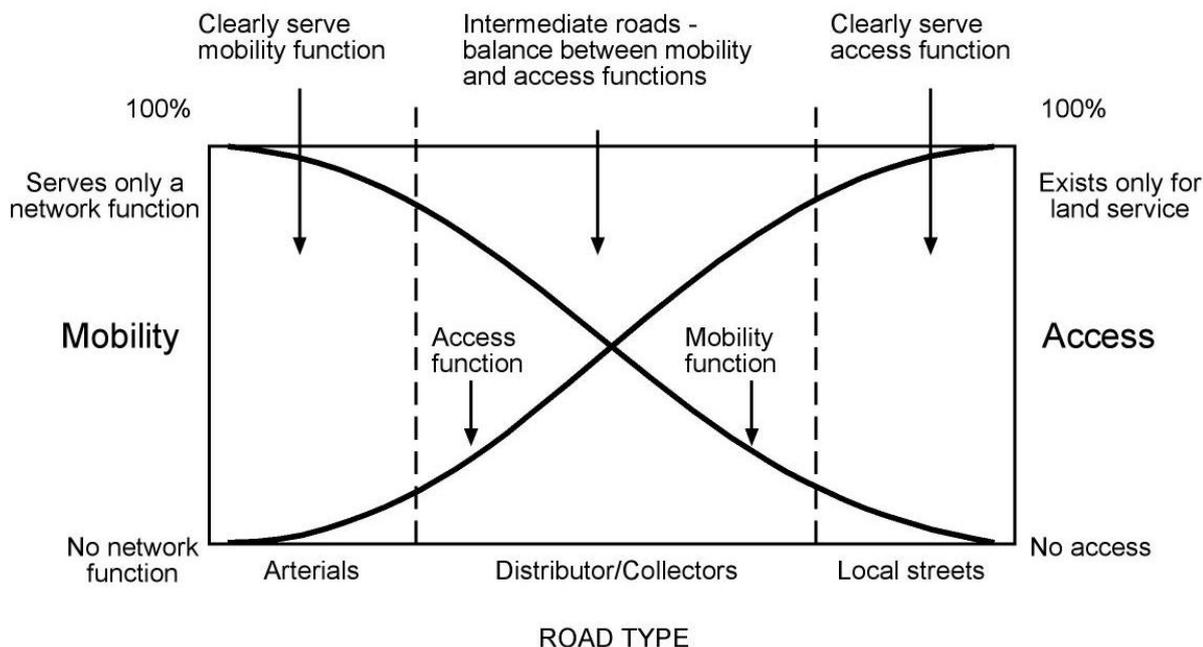

The primary function or balance of different functions may be reflected in the classification of a road. In its purest form, road classification may consist of two basic road types which have fundamentally different traffic and environmental goals:

- arterial roads, the main function of which is to provide for the safe and efficient movement of people and freight
- local roads, which provide direct access to abutting land uses and which contribute to the overall functioning of areas bounded by arterial roads or other barriers. The basic function of a local road is to provide a good environment in which to live or conduct a business and to enable vehicular access to abutting land.

Historically, Australasian practice for the management of the road environment has been based on a mixed function of mobility and access, as illustrated in Figure 3.1. Some road classification systems attempt to reflect the mixed function and the design and management of the roads, and their networks also need to reflect the mixed function.

Figure 3.1 demonstrates that for some roads there are competing legitimate demands for a strong emphasis on mobility on the one hand, and increased emphasis on local amenity on the other. These competing demands require a balance between mobility and access.

Figure 3.1: Road type and function: mobility vs access

Most road classification systems include additional categories which reflect this mixed function. The design and operation of streets and roads reflect their roles in the general road traffic, public transport, cycling and walking networks, and their linkage to local networks. The design and traffic management of the roads must also reflect the mixed function.

The mixture of functions met by roads across a network is usually expressed as a functional hierarchy. The basis of a traffic management plan for a road network is the development of an agreed road hierarchy by means of which roads can be classified according to their existing, or their intended function. The operational, safety or other benefits that are pursued by traffic management actions must be assessed in the context of the functional hierarchy of roads within the network.

The function of a road is reflected in traffic characteristics such as volume, speed, and mix of vehicular and non-motorised traffic. The function should also be reflected in the physical characteristics of the road, such as formation width, number and width of lanes, proximity and protection of potential hazards.

Roads, generally, are classified on the basis of how they currently operate, but consideration should also be given as to how they are expected or desired to function in the future, in terms of the relative significance of the traffic function versus the land access function for a particular road, and its desirable operating speeds and traffic volumes.

The management of different road classes may require the needs of a particular road user group (e.g. public transport users, cyclists, pedestrians) to be given priority, or for the needs of different users to be 'balanced'. Where available road space is limited, this may mean that a particular transport mode is favoured over others.

For some roads there are competing legitimate demands for a strong emphasis on mobility on the one hand, and increased emphasis on local amenity on the other. This inevitably creates challenges with respect to the traffic management required to achieve an appropriate balance between the mobility and access functions on many of these roads.

The importance of functional road classification, as a fundamental concept in traffic management, is developed in more detail elsewhere in this Guide, particularly Parts 4, 5, 8 and 9.

## 4. Basic Elements of Traffic Management

Observed traffic flow arises from the characteristics of transport demand, road user behaviour, vehicle performance, and road and weather conditions. Traffic management requires an awareness of these basic elements, an understanding of the characteristics of traffic flow, an ability to measure and analyse traffic conditions, and expertise in identifying and implementing appropriate techniques to influence and control traffic flows to meet objectives.

### 4.1 Traffic Theory and Analysis

The basic variables used to describe a stream of traffic are its volume, speed and concentration (or density), from which other descriptive variables can be derived. There are observed fundamental relationships between these variables which can be described mathematically and graphically. Different combinations of the variable values give rise to different traffic conditions. Monitoring and analysis of traffic conditions, to assess and enhance road capacity and develop effective operational initiatives, is fundamental to traffic management.

These matters are dealt with in Part 2 and Part 3 of the Guide.

### 4.2 Traffic Control Devices

The movement of people and goods can involve a degree of conflict between objectives and some traffic conditions may exceed desired characteristics of operation. Such circumstances require the imposition of constraints on the movements of road users so as to achieve behaviour or operation which is in accord with a general policy or strategy on traffic management. Traffic control devices such as signals, signs, and markings are the engineering tools used for achieving the necessary balance among mobility, safety, amenity, accessibility, etc.

General techniques for dealing with traffic operational matters are covered in Part 9 of the Guide and more detailed guidance on the development and use of control devices is given in Part 10.

### 4.3 Legislation, Standards and Guidelines

The primary requirements for road user behaviour are set down in various Acts, regulations and rules in the various jurisdictions in Australasia. These specify mandatory requirements enforceable under law and often call up more detailed specifications set down in formal standards agreed by government and industry. Further guidance on the practical implementation of facilities to support and give effect to traffic law is given in many guidelines documents issued by jurisdictional governments.

A fundamental requirement of effective and safe traffic management is that similar situations across the several jurisdictions are treated in a consistent way. In Australasia, in addition to the *Guide to Traffic Management*, consistency in traffic management and engineering practice is promoted through several key documents, namely:

- the Australian Road Rules (2006)
- Australian Standards, particularly AS 1742 – *Manual of Uniform Traffic Control Devices set 2014 (15 Parts)*
- Land Transport Rule: Traffic Control Devices 2004 (New Zealand)
- Land Transport (Road User) Rule 2004 (New Zealand)
- New Zealand Traffic Control Devices (TCD) manual (NZTA 2008).

In practice these are largely adopted by the various jurisdictions, which may also produce supplementary guidelines and manuals to accommodate specific legislative or physical situations and are followed by local government bodies.

## 4.4 Application

The basic elements of traffic management practice – theory, data, analysis, control devices, regulations and standards – are applicable to the wide range of circumstances encountered in practice. The information in the Guide has been assembled to provide guidance for practitioners dealing with traffic management on arterial or local roads, in residential or commercial precincts and in urban or rural areas.

In applying the principles and tools to meet set objectives, typically on defined routes or in defined areas, it is important that broader strategic approaches across the road network are also understood and guide the process. These may relate to freight or public transport issues, for example, or the transport and traffic consequences of major land use developments in a region. Broad network management issues are covered in Part 4 of the Guide. Specific guidance on managing traffic on routes and at intersections is given in Part 5 and Part 6.

Traffic management may also be applied to a range of defined areas, from local residential areas to commercial and civic precincts, and major transport nodes such as ports and inter-modal transfer centres. Part 7 of the Guide covers issues relating to major activity centres and Part 8 deals with local area traffic management.

An important aspect of traffic management in central urban areas, both strategically and operationally, is the issue of parking. This is covered in Part 11 of the Guide. Land use developments, particularly those in urban areas, can have major implications for the generation and management of traffic. These impacts are addressed in Part 12.

In many cases, the nature of a traffic problem, the measures which might be applied, and the likely effectiveness of those measures will not be readily apparent. A range of alternative treatments must therefore be developed and analysed. In developing a traffic management scheme and eventually implementing initiatives or control measures, the following general procedure can be applied:

1. Confirm overall objectives for the study area and general issues to be addressed.
2. Conduct a survey of the network, route or study area, including traffic volumes, travel times, and traffic problem locations.
3. Identify different interest groups, their views and objectives.
4. Identify the desired objectives of the traffic management scheme, together with measures of their achievement.
5. Develop alternative proposals.
6. Conduct initial assessment of the various proposals, including prediction of changes in traffic flows, impacts on all relevant groups and general performance of each scheme relative to the stated objectives.
7. Select the preferred scheme and undertake more detailed analysis and design of that scheme.
8. Implement the scheme on a trial basis, monitoring all possible feedback and modifying the design as appropriate.
9. When satisfactory operation is indicated, complete full implementation of the scheme.
10. Undertake an appropriate evaluation of the scheme so that its effects can be formally assessed and documented.

## 4.5 Road Environment Safety

Traffic management, together with relevant planning, design, construction, and operational practices, is a fundamental tool whereby the road environment can be made safer. It directly affects the physical road environment in which road users operate, and thereby influences the behaviour of road users. In addition to the other Parts of the Guide, guidance relevant to achieving a safe road environment is contained in several other Austroads Guides.

Part 13 of the Guide introduces Safe System principles and approach. It summarises and draws together safety-related guidance material in the context of the strategic application of traffic management practices to achieve safer operation within the road and traffic environment. For the topics presented in Part 13, cross-references are given to their treatment in the relevant Parts of other primary Guides particularly the Guide to Road Safety and the Guide to Road Design.

## 5. Use of the Guide

This Guide is intended to be a primary reference document for practitioners involved in traffic planning and traffic management. However, it should be read in conjunction with other Austroads Guides, relevant Australian/New Zealand Standards, relevant strategies and action plans, individual road agency policies and guidelines, and other relevant texts.

The references in this Guide to relevant Parts of other Austroads Guides, particularly those on *Road Design*, *Road Safety* and *Road Transport Planning*, are especially important. Reference should also be made to the *Guide to Asset Management*, particularly Part 3 that places road use strategies in the context of broader asset management strategies and the *Guide to Road Tunnels*, particularly Part 2 that covers special requirements of the planning, design and commissioning of road tunnels.

Each Part of the Guide provides guidance supported by appendices and references to resource materials. It is expected that, for the experienced engineer or practitioner, the central guidelines will provide the necessary key information. Less experienced designers or students will find the resource documents particularly useful.

Those wishing to obtain an overview of the traffic management discipline will find this *Part 1: Introduction to Traffic Management* a useful summary.

Practitioners seeking a summary or refresher on the underlying theoretical and analytical aspects of traffic flow can refer to *Part 2: Traffic Theory* and *Part 3: Traffic Studies and Analysis*.

Practitioners dealing with the management of traffic on arterial routes should refer to *Part 5: Road Management* and *Part 6: Intersections, Interchanges and Crossings*.

Those concerned with strategic traffic management across road networks should refer to *Part 4: Network Management*. More detailed guidance on the management of traffic operations and the implementation of various control devices is given in *Part 9: Traffic Operations* and *Part 10: Traffic Control and Communication Devices*.

Planners and those associated with the design and development of local areas would find relevant guidance in *Part 8: Local Area Traffic Management*. For traffic management issues relating to commercial and civic areas, reference should be made to *Part 7: Traffic Management in Activity Centres*, *Part 11: Parking* and *Part 12: Traffic Impacts of Developments*.

For practitioners concerned with the road safety aspects of traffic management in the road environment, *Part 13: Road Environment Safety* provides an informative overview and references to relevant Parts of other Austroads Guides.
